

## ABSTRACT

A data listing contains multiple data entries. The data listing is analyzed to determine the number of data entries in the data listing. If the data listing has at least N data entries, then an index mark is added to every Nth entry in the data listing. The data listing may be printed or displayed on a computing device, including the added index marks. In one implementation, N is five. The index marks may be symbols or other distinguishing characteristics added near the appropriate data entry. The data listing can be a printer menu hierarchy including multiple levels of data entries.
